

1 STATOR

2
3 Related Art

4
5 The invention is based on a stator according to the definition of the species in
6 Claim 1.

7
8 A stator that has a plastic coating was made known previously in EP 0 880 215
9 A2. The plastic coating is applied by means of injection molding and,
10 simultaneously, receptacles can be formed as well that simplify the installation of
11 a bearing or a connector.

12
13 The individual laminations of the stator must be joined into one laminated stack
14 before injection molding, however. Furthermore, the laminations must be pressed
15 together on the respective stator pole teeth during injection molding so that no
16 gaps form between individual laminations into which the plastic can enter.
17 Additionally, stator pole teeth are connected to each other in permeable fashion.

18
19 Advantages of the Invention

20
21 In contrast, the stator according to the invention having the characteristic
22 features of claim 1 has the advantage that the manufacture of a stator is made
23 easier in simple fashion, by way of which the stator of an electric motor can be
24 assembled more easily, quickly, and favorably.

25
26 Advantageous further developments and improvements of the stator named in
27 claim 1 are possible due to the measures listed in the dependent claims.

28
29 For the installation of the stacks of individual laminations on the core ring, it is
30 advantageous that the core ring have a hook-shaped projection for each stack of

individual laminations that at least partially encompasses the stack of individual laminations and forms a positive connection.

For the installation of the stacks of individual laminations on the core ring, it is advantageous that the core ring have a protuberance that can be guided *[word missing]* a groove of the stack of individual laminations, because the stack of individual laminations can then be attached in centered fashion.

It is advantageous to produce the plastic coating of the stator by means of injection molding.

For the installation of coils on the at least one lamination, it is advantageous that the lamination have projections extending radially outward, onto which the coils can be slid.

An advantageous embodiment of the invention is given by the fact that a coil form is integrally molded around the projections of the laminations, because this simplifies the installation of coils on the stator.

For the process of winding of a coil on the coil form, it is advantageous if the plastic coating have at least one winding support point that simplifies the gripping of the stator, and if a lowermost winding plane of the coil form only touches the coil form, because the coil form is then freely accessible for the winding process, and a winding head of a winding machine can encircle the coil form freely.

If the coil form or the plastic coating also has a receptacle, furthermore, an insulation displacement connection having a coil wire and external connections can be produced in advantageous fashion.

1 It is advantageous to design the projections of the lamination so that an external
2 member can be slid onto the lamination and held by the projections by means of
3 a non-positive connection or by means of a bayonet coupling.

4
5 The formation of a laminated stack out of individual laminations can furthermore
6 be advantageous.

7 8 Brief Description of the Drawing

9
10 Exemplary embodiments of the invention are shown in the drawing in simplified
11 form and described in greater detail in the following description.

12
13 Figure 1 shows a core ring,
14 Figure 2 shows a core ring having laminations,
15 Figure 3 shows laminations having a plastic coating and coil forms,
16 Figure 4 shows a stator according to the invention,
17 Figure 5 shows a stator according to the invention having a punched grid, and
18 Figure 6 shows a partial representation of an arrangement of an external
19 member on a projection of the lamination.

20 21 Detailed Description of the Exemplary Embodiments

22
23 Figure 1 shows a core ring 70. The core ring 70 has at least one hook-shaped
24 projection 77 for each stack of individual laminations 16 (Figure 2) that extends in
25 the direction of a centerline 3 on an outer surface of the core ring 70. The
26 projection 77 at least partially encompasses a foot of a stack of individual
27 laminations 16 and forms a positive connection. In this example there are two
28 projections 77 for each stack of individual laminations 16.

29
30 The core ring 70 has at least one protuberance 74 between these two projections
31 that extends in the direction of the centerline 3 on the outer surface of the core

ring 70 and in which a groove 58 of the stack of individual laminations 16 catches.

The core ring forms a watertight inner channel 27 through which a medium, e.g., a liquid medium, can be directed.

Figure 2 shows laminations 1 in the form of the stack of individual laminations 16 or a lamination 18 that are located on the core ring 70. The same reference numerals are used in the following figures as in the preceding figures for identical or equally-acting parts. The projections 77 and the stack of individual laminations 16 are shaped in relation to each other in such a fashion, e.g., the projections 77 have radially different heights, so that the laminations can be installed in only one certain fashion. After the application of a plastic coating 22, by means of injection molding, for example, the stack of individual laminations 16 is held together by means of this partially present plastic coating 22. Preassembled coils can be slid onto the stator pole teeth.

One component produced in this fashion is a stator for a fluid pump, for example, wherein the projections 5 form stator pole teeth.

Lower electrical losses during the operation of a pump result due to the fact that the stator pole teeth are designed separate from each other and permeable.

Figure 3 shows a further development of a laminated stack 18, having a plastic coating 22 from Figure 2.

A coil form 34 has been integrally molded around the projections 5, which form stator pole teeth. These can be produced in one working step using the application of the plastic coating 22. A coil 45 (Figure 5) of electrically conductive wire can be wound on the coil form 34. This coil 45 encloses the projection 5 and serves to magnetically excite a rotor (not shown). A connection must be

1 produced for the external electrical power supply of the coil 45. This takes place,
2 for example, by means of a receptacle 38, in which an insulation displacement
3 connection between one end of coil wire and an external or further electrical
4 connecting lead can be produced. This mechanical connecting is very simple and
5 rapid compared to a soldering for the connection of electrical leads.

6
7 Figure 4 shows a stator 20 according to the invention. A winding 45 has been
8 wound on the coil form 34. The coil form 34 has a lowermost winding plane 51
9 that is indicated by a line that is closest to the centerline 3. The lowermost
10 winding plane 51 touches the plastic coating 22 only at the one respective coil
11 form 34. The coil form 34 is therefore freely accessible for the winding procedure,
12 and a winding head of a winding machine can encircle the coil form 34 freely.

13
14 On the plastic coating 22 or, as in this exemplary embodiment, the coil form 34
15 has a winding support point 54 for better gripping of the lamination 18 during the
16 winding procedure. In this example, the receptacle 38 serves as winding support
17 point 54.

18
19 One end of a coil wire 48 of the winding 45 is located in the receptacle and
20 squeezed in a slit 49, for example.

21
22 Figure 5 shows a stator 20 according to the invention according to Figure 5
23 having a punched grid 60 that extends from one receptacle 38 to the other
24 receptacles 38 and forms a neutral point of the windings 45.

25
26 Figure 6 shows an annular external member 30 that can be slid onto a stack of
27 individual laminations 16 or a laminated stack 18. The projections 5 thereby
28 extend in the radial direction so far that the external member is held on the
29 laminated stack by means of non-positive engagement. This takes place, for
30 example, because the projection 5 is displaced relative to the centerline 3, and
31 the external member 30 can therefore be screwed onto a conical surface.

1

2 The external member 30 forms a magnetic return element or a part of the motor
3 housing. The external member 30 can also be formed out of individual
4 laminations.
